# The different properties of the coords object

In the previous example, we used the `coords` property of the position passed as an input parameter to the callback function. This `coords` object has many properties:

| Properties of the coords object | |
|---|---|
| **latitude** | The latitude of the position |
| **longitude** | The longitude of the position |
| **altitude** | The altitude of the position |
| **accuracy** | The accuracy of the measure of the longitude and latitude (in meters) |
| **altitudeAccuracy** | The accuracy of the measure of the altitude (in meters) |
| **heading** | gives the orientation relative to north, in degrees |
| **speed** | current speed in meters/second |

Not all these values may be available in all Web browsers. When one of these properties is `null`, it means that it is not available.
